## 1 Standard ideogram plots

`ideogram` displays cytogenetic banding information in the plot margin and calls a secondary plotting function to display associated data at the same relative scale. Cytogenetic data for human, mouse, and rat genomes are currently included. We have written this due to a large volume of traditional cytogenetic data currently available.

The data is arranged by associating feature identifiers to genomic location using a `chromLoc` annotation object build using the `buildChromLocation` from the annotation package. As such is a vector of data is to be plotted, the `'names'` attribute of the vector MUST to contain the gene identifiers. Likewise if a matrix of data is to be plotted, the `'rownames'` attribute of the matrix MUST to the gene identifiers.

To date, `'plot'` can be called for vector data, while `'maplot'` and `'image'` can be called for matrix data. Most additional plotting arguments can be passed down via .... However, the ideogram function plots the axis independently. Therefore arguments like `'cex.axis'` are not passed via the `'plot'` function. The `'cex.axis'`, `'col.axis'`, and `'font.axis'` are intercepted from ... and redirected to the `'axis'` call. Other parameters that effect the axis should be set via `'par'`.

Below some example data is set up to plot an ideogram.

```
> if (require(hu6800) && require(golubEsets)) {  
+   library(golubEsets)  
+   library(hu6800)  
+   library(ideogram)  
+   library(annotate)  
+   hu.chr <- buildChromLocation("hu6800")  
+   ex <- golubTrain@exprs[, 1]  
+   colors <- rep("black", times = length(ex))  
+   colors[ex > 10000] <- "red"  
+   pts <- rep(1, times = length(ex))  
+   pts[ex > 10000] <- 2  
+ }
```

Loading required package: hu6800  
Loading required package: golubEsets  
Loading required package: Biobase

Welcome to Bioconductor

Vignettes contain introductory material.  
To view, simply type 'openVignette()' or start with 'help(Biobase)'.  
For details on reading vignettes, see the openVignette help page.

Loading required package: annotate

```
> if (require(hu6800) && require(golubEsets)) {  
+   ideogram(ex, hu.chr, chr = "1", col = colors, pch = pts,  
+     font.axis = 2, cex.axis = 1)  
+ }
```

## 2 Interactive ideogram plots

Many investigators have their favorite region of interest, and would find it useful to dynamically interact with their ideogram plots. This has been added through the `ideograb` function. This has made an easier way for researchers to identify specific genes within cytogenetic regions of interest.

`ideograb` has been written to take an ideogram call as one of its arguments. Two points are first clicked on to determine the coordinates of a rectangular region. All names of genes within that region are then returned in a vector.

## 3 Using ideogram with other packages

Many useful packages can be used in conjunction with `ideogram`. In this section, we will show how to use the *limma* package to determine differentially expressed genes and then plot them with `mideogram`. Please see the *limma* tutorial for more information.

The `topTable` function returns a data frame with information about differentially expressed genes. Here we show how you would use the results of `topTable` ("t") and a `chromLocation` object that contains chip-specific annotation information. In this case, we need to create a vector of values with the names attribute set to the corresponding gene name. A colors vector is created with "gray" as the base color, and then altered to accentuate the values with an absolute value of greater than 1. Please note, the actual data was not included with this package to save space. This is only example code.

```
data <- t$M
names(data) <- rownames(t)
colors <- rep("gray",length(data))
colors[which(data>1)] <- "red"
colors[which(data<(-1))]] <- "blue"
names(colors) <- names(data)
mideogram(data,chromLocation,xlim=c(-5,5),col=colors,pch=20)
```
